

Introduction of High Performance Computing

Assignment 1

Alberto Presta

March 2019

Exercise 1 - Parallel approximation of π

the goal of the exercise is to write a code which approximates π . In order to do this, we will calculate, using midpoint formulam the following integrate:

$$\pi = 4 \cdot \int_0^1 \frac{dx}{1+x^2} = \sum_{i=0}^{N-1} f(x_{i+\frac{1}{2}})$$

First of all, we have written a serial code which calculates this integrals and then we move to an "multi-thread" approach using three different commands in order to avoid *race condition*:

1. Critical.
2. Atomic.
3. Reduction.

Code and Results

After having written the code (which is the github repository), we ran it on Ulisse with different number of threads and we have reached the following results:

Figure 1: These three plots show to us how time decreases when the number of threads increases: the "left-figure" represents the code with the command *reduction*, the "central" one the code with the command *critical* and right one the code with the command *atomic*.

When we increase the number of threads, obviously time decreases in a very fast way. We notice also that the three different commands give to us almost

the same result: the only different is that using critical things get a little bit worst with 20 threads. Obviously we ran also the serial program, reaching truly worst result:

```
1 value of pi: 3.141593
2 time for approximating pi with serial code: 18.159840 seconds
```

Exercise 2 - OpenMp Loop Schedule

In this exercise the main goal is to create a visualization of two different schedules using different chunks. I implemented the 6 requested schedules aind I run my program in a Ulysses node, using 10 threads (The c-code and the script can be found in the github). Here we are the output:

```
